

# Liverpool City Region's Coastal Designated Sites Evidence Strategy Workshop

## Workshop Session 1: Evidence baseline and issues - where are we now?

### SUMMARY

The aim of this workshop session was to determine which forms of evidence are currently being collected by which organisations, to identify key gaps in our evidence base and to propose opportunities for filling these gaps.

The main evidence gaps were identified as follows:

**Biological (habitats & species):** Information on mobile species eg migratory fish and eels, birds and cetaceans and how they use the coastal waters and estuary (e.g. nursery grounds for fish, bird feeding areas; availability of prey resources); knowing the location and use of functionally-linked land; habitat quality – not just extent; and understanding cause and effect.

**Water Quality:** Ecological status of water bodies; upstream and diffuse pollution; links between groundwater and the estuary; impacts of contaminated land / historical contamination; understanding of the impact of changes in water quality on habitats and species; knowledge of non-surveillance water bodies eg the Mersey.

**Sediments and coastal processes:** Historical contaminated sediment (extent, source and pathways); response time for habitats and species to show effects of historical pollution; understanding the impacts of dredging on historical contaminants in sediment; quantifying sediment movement from offshore; linkages between sediments / coastal processes and fisheries; success of dune restoration projects; impacts of climate change.

**Human activities and impacts:** Understanding shifting baselines eg bird populations; impact of land management on bird species; evidence to show whether agri-environment schemes are effective; success of mitigation schemes for developments; impacts of other activities / new developments on fisheries resources; understanding thresholds and cumulative impacts; recreational disturbance and use; understanding physical modifications and impacts on water quality.

Solutions for filling these gaps included: the use of citizen science, volunteer networks and partnerships (eg catchment partnerships); directed research in collaboration with universities; using evidence collected by industry and sea users (eg ports or anecdotal information from fishermen); making better use of mobile technology; making more of the local records centres (using them more and encouraging others to use them and submit data); the creation of a 'pressure map' to identify all human activities taking place in the area; and the addition of a condition into consents / licences to ensure that success of mitigation is monitored and results are submitted.

Some key points raised were that a lot of evidence is being collected by the different organisations but we need to ensure that this is fit for purpose. We need to be better at sharing evidence across different sectors and a big gap is actually in the collation and synthesis of all of these data to understand what they mean.

## ANNEX 1

### Key Points:

- It's not clear what's required and what it means:
  - It's not clear what the key issues are for the LCR coastal areas: have these been synthesised somewhere?
  - It might be that the data are all there but it's the synthesis of these data that is missing.
  - A big gap is an overview and meaning of all of the data – there are lots of data out there but no one is looking at what they are showing us and the implications of this.
  - Need some more joined-up studies to collate all of the different datasets
  - Local Record Centres are key in terms of collating data and public engagement / communication
- Evidence needs to be 'fit for purpose':
  - The time-scales for some evidence / projects can be much shorter than for others – how long do data remain valid for?
  - Some datasets can be 40-50 years out of date
  - A lot of historical data may not be valid for evidence base for a new development
  - In some cases it can be difficult to determine whether the evidence supplied by developers is fit for purpose.
  - Keeping evidence up to date is the most crucial thing especially for habitats (as it needs to be more standardised).
- Sharing evidence:
  - Private sector can be reluctant to share raw data; consultancies often don't share GI data – these data could be used for other purposes
  - Could ask developers to share data as part of their Licence requirements
  - But need to be careful if data are collected for a specific purpose and then used to answer other questions; risks of data being misused and therefore need to be caveats associated with the data.
  - Highlights importance of good metadata
  - Evidence that is shared needs to be used responsibly.
  - Commercial sensitivities need to be taken into account
- Volunteer networks / Citizen science
  - Everyone uses WeBS data – there needs to be more support/collaboration for WeBS
  - Other examples of citizen science: 'River Guardians' on the lower Mersey; Rivers Trust nationally are collecting water quality data via worldwide scheme 'Freshwater Watch'; use of volunteers on the Sefton Coast to help support unpopular management decisions.
  - Need to be aware of bias when using volunteers – studies need to be robust

- Feedback is very important when volunteers are used: how are the data collected by the volunteers being used? What does it show?
- Learn from others
  - The LCR isn't unique: need to keep an eye on other similar regions eg Clyde and Severn – can we learn from them?
